

**Teaching goals:** The student is able to

- define regular expressions and the matching languages
- construct a regular expression for a language given in set notation
- convert a regular expression to a finite automaton
- convert a finite automaton to a regular expression using state elimination
- define two-way finite automata, construct a two-way FA for a given language

IN-CLASS PROBLEMS

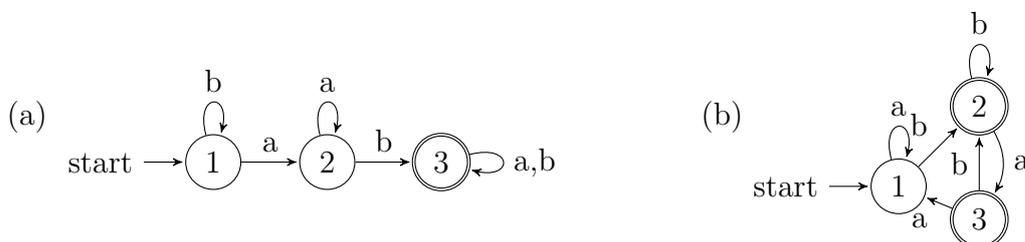

**Problem 1** (Constructing regular expressions). Find regular expressions representing the following languages over  $\Sigma = \{a, b\}$  consisting of words that:

- (a) start with ‘abba’,
- (b) start with ‘ab’ and end with ‘ba’,
- (c) contain ‘abba’ or ‘bab’ as a subword,
- (d) do not contain ‘aa’ as a subword,
- (e) contain an even number of a’s,
- (f) the first letter is the same as the last.

**Problem 2** (Regex to automaton). Construct NFAs recognizing the languages described by the following regular expressions:

- (a)  $a^2 + b^2 + ab$
- (b)  $a + b^*$
- (c)  $(ab + c)^*$

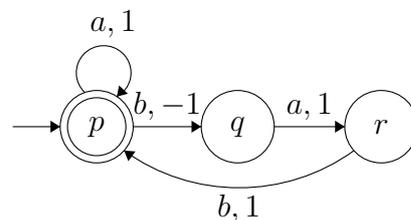

**Problem 3** (Automaton to regex). Construct regular expressions for languages recognized by the following automata.

**Problem 4** (Convert a 2-way automaton). Consider the following two-way DFA.

- (a) Determine the language it recognizes.
- (b) Determine the functions  $f_w$  and the congruence  $\sim$  for all  $w$  of length  $\leq 4$ .
- (c) Convert it to an equivalent one-way automaton.

	a	b
$\rightarrow *p$	$p, 1$	$q, -1$
$q$	$r, 1$	
$r$		$p, 1$

**Problem 5** (Constructing 2-way automata). Let  $L$  be a regular language over  $\Sigma$  and  $\# \notin \Sigma$ . Construct a two-way finite automaton accepting the given language:

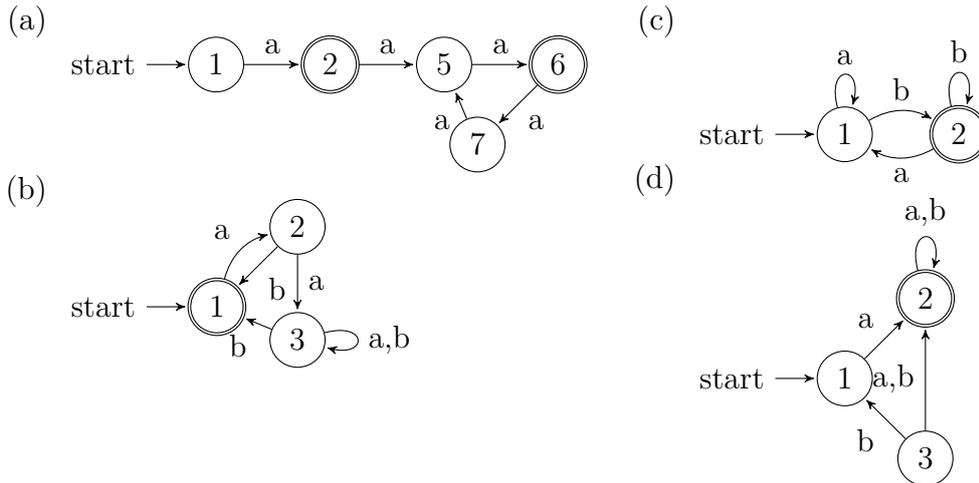

- (a)  $L' = \{\#w\# \mid ww^R \in L\}$
- (b)  $L' = \{\#w\# \mid (\exists u \in \Sigma^*)(wu \in L \wedge |w| = |u|)\}$

## EXTRA PRACTICE AND THINKING

**Problem 6** (Regex to automaton). Construct finite automata accepting languages described by the following regular expressions:

- (a)  $ab + ba$  (c)  $((ab + c)^*a(bc)^* + b)^*$   
 (b)  $((ab + c) + a(bc)^* + b)^*$  (d)  $(01^* + 101)^*0^*1$

**Problem 7** (Automaton to regex). Construct regular expressions for languages accepted by the following automata.

**Problem 8** (Complement of a Regular Expression). Consider the following regular expression over the alphabet  $\Sigma = \{a, b\}$  and let  $L = L(R)$ .

$$R = ((a + b)(a + b))^*ab$$

- (a) Construct a *nondeterministic* finite automaton  $A$  (as small as possible) recognizing  $L$ .  
 (b) Use the subset construction to convert  $A$  to a *deterministic* finite automaton  $B$ .  
 (c) From the automaton  $B$ , construct a DFA  $C$  recognizing the *complement* of  $L$ .

**Problem 9** (Testing equivalence of regular expressions). Describe an algorithm to test equivalence of two regular expressions. Apply it to  $(a + b)(a + b)^*$  and  $a(a + b)^* + b(a + b)^*$ .

**Problem 10** (Are regular expressions regular?). Fix a finite alphabet  $\Sigma$ . Is the language consisting of all regular expressions over  $\Sigma$  a regular language?

**Problem 11** (Without 2-way automata this is hard). Given a DFA  $A$ , design an NFA recognizing the language  $L' = \{\#w\# \mid ww^R \in L(A)\}$ . (Do not use two-way DFAs.)

## BONUS: AUTOMATA WITH OUTPUT

**Problem 12** (Mealy and Moore machines: definition and conversion). Define Mealy and Moore machines. Design a conversion procedure between them.

**Problem 13** (Mealy and Moore machines: construction). Design a Mealy or Moore machine that implements the operation: (a) bitwise sum of 0-1 vectors, (b) bitwise product of 0-1 vectors, (c) arithmetic sum, when we read numbers backwards (1st bit least significant).
